**TITLE**

Isotope labeled camptothecin derivatives

5 **FIELD OF THE INVENTION**

The present invention pertains to the field of isotopically labeled compounds useful in the absorption, distribution, metabolism, excretion (ADME), pharmacokinetic and pharmacodynamic studies. The invention relates to, in particular, the preparation of stable labeled camptothecin analogs starting from commercially available stable labeled precursors at high isotopic enrichment.

**BACKGROUND OF THE INVENTION**

15 Camptothecin is an alkaloid derived from the Chinese tree *Camptotheca acuminata*. Camptothecin and its derivatives are unique in their ability to inhibit DNA Topoisomerase, by stabilizing a covalent reaction intermediate termed the cleavable complex which ultimately causes tumor cell death. 20 Topoisomerase is responsible for the winding/unwinding of the supercoiled DNA composing the chromosomes. If the chromosomes cannot be unwound, transcription of DNA message cannot occur and the protein cannot be synthesized, it ultimately causes cell death. Application of camptothecin 25 in clinic is limited due to serious side effects and poor water-solubility. At present, some camptothecin analogs, either semi-synthetic or synthetic drug based on camptothecin, have been applied cancerous therapy such as topotecan and irinotecan.

30 Since its approval in the United States in 1996, irinotecan hydrochloride trihydrate (CPT-11, CAMPTOSAR<sup>®</sup>, injection, Pharmacia Corp.; Peapack, NJ) has undergone extensive clinical evaluation. In the past five years, the focus of development has evolved from evaluation of single-agent

activity in refractory disease settings to evaluation of front-line irinotecan-based combination chemotherapy regimens and integration of irinotecan into combined modality regimens. Important studies have been performed  
5 clarifying the role of irinotecan treating colorectal and other gastrointestinal cancers, small cell and non-small cell lung cancer, and a variety of other malignancies.

CPT-11 has shown activity against a variety of tumour types, particularly refractory colorectal tumours, and it  
10 is used for the treatment of various forms of cancer. Its primary use is in the treatment of colon cancer, particularly advanced colon cancer. It is also of interest for treatment of other cancers, however, and mention is made of cancers of the lung, the stomach and the pancreas.

15 The antitumor activity of CPT-11 is attributed to an active metabolite, 7-ethyl-10-hydroxy 20(S) camptothecin (SN-38), which is produced after enzymatic cleavage by carboxylesterases in the liver, small intestine and plasma.

Accurate, sensitive and specific measurement of  
20 camptothecin analogs and their metabolites such as, for example, irinotecan and its metabolite SN-38 may allow to carry out precise pharmacokinetic and pharmacodynamic analysis of these products in biological samples such as, for example, animal and human plasma, urine, bile, tissues  
25 and in vitro cell culture media.

For example, one of the most convenient method for daily routine analysis was obtained by using automated sample handling procedure followed by liquid chromatography (LC) and mass spectrometry detection (MS). One crucial aspect of  
30 a reliable and validated analytical method is the availability of a suitable internal standard. The addition of known amount of an internal standard to the unknown sample is a well-known and widely used procedure that can

compensate for losses of the compound of interest during sample workup. According to this approach, any loss of the compound of interest can be determined by the loss of an equivalent fraction of internal standard. The precision and accuracy of this approach is strongly dependent on the structural similarity between the compound of interest and the internal standard. As a consequence it is generally agreed that the stable isotopically labeled analogues with the same molecular structure of a compound are the best internal standards for liquid chromatography-mass spectrometry (LC-MS) assay. In addition the internal standard should have preferably a molecular weight at least three mass units higher than that of the non-labeled compound of interest.

There is therefore a need of stable isotope labeled camptothecin analogs especially irinotecan and its active metabolite SN-38, in order to improve the accuracy, sensitivity and specificity of the analytical methods to determine the non labeled parent drugs or their metabolites in biological samples. The following invention fulfills such a need by providing stable labeled camptothecin derivatives comprising irinotecan and SN-38.

#### DETAILED DESCRIPTION OF THE INVENTION

It is therefore an object of the present invention stable labeled camptothecin analogs and a method for their preparation starting from commercially available stable labeled precursors at high isotopic enrichment and non-labeled intermediates that can be synthesized according to well known methods.

 $R_{22}$ ,  $R_{23}$ ,  $X_{10}$ ,  $X_{11}$ ,  $X_{12}$ ,  $X_{13}$ ,  $X_{14}$ ,  $X_{16}$ ,  $X_{17}$ ,  $X_{18}$ ,  $X_{19}$ ,  $X_{20}$ ,  $Y_1$   
 and  $Y_2$  are as above described for the compound (X)  
 and, converting a compound of formula (VII) into the  
 corresponding free base with the same formula (VII)

The processes described above are particularly advantageous  
 as they enable the selective preparation of a variety of  
 compounds of formula (I) isotopically labeled. In addition,  
 they enable the preparation of the desired derivatives in  
 high yields and with a high degree of isotopic enrichment.

According to step (a) of the above process, the reaction  
 between a compound of the formula (II) with a compound of  
 the formula (III) is carried out under an inert atmosphere,  
 for example under nitrogen, by heating preferably at  $90^{\circ}\text{C}$  a  
 mixture of the above two compounds with  $\text{BCl}_3$  and a Lewis  
 acid, such as for example  $\text{AlCl}_3$  in an inert organic  
 solvent, such as for example a mixture of dichloromethane,

toluene and dichloroethane. It is preferred to pre-mix a compound of formula (II) and  $\text{BCl}_3$  in a preferred molar ratio of 1 to 1.1 at low temperature, such as for example  $4^\circ\text{C}$ . It is preferred to pre-mix a compound of formula (III) and the Lewis acid in a molar ratio of 1 to 2+20, preferably 1 to 3, at low temperature, such as for example below  $10^\circ\text{C}$ . The molar ratios between a compound of the compounds of formula (II) and of a compound of a formula (III) are preferably 1 to 4. The progress of the reaction is checked by an analytical method, for example thin layer chromatography or high performance liquid chromatography or mass spectrometry, and the disappearance of the compound of the formula (II) is complete generally within about 4 hours. The reaction mixture is then added with water and heated, for example at  $80^\circ\text{C}$  in order to allow the formation of a compound of formula (IV). The progress of this stage of the reaction is checked by an analytical method, for example thin layer chromatography or high performance liquid chromatography or mass spectrometry, and is complete generally within about 30 minutes. The two-phase mixture is cooled, preferably at room temperature, for example at  $25^\circ\text{C}$ . The organic phase is extracted with an acidic aqueous solution, for example 1N hydrochloric acid. All the collected aqueous phases are pooled and added with a base, for example a 35% aqueous solution of NaOH, up to basic pH, for example 8+9. This mixture is extracted with a non-water miscible solvent, such as for example dichloromethane, and all the organic extract are pooled. This solution is dried over an inorganic salt, such as for example sodium sulfate, and the solvent is evaporated, for example with a rotating evaporator. The so obtained crude material containing a compound of formula (IV) is preferably purified by using techniques well known in the art. For example, preparative-column chromatography using silica gel along with

appropriate eluants such as mixtures of organic solvents may be used to effectively purify the desired compound so as the following cleavage of a compound of formula (IV) is successfully carried out.

5

According to step (b) of the above process, a compound of formula (IV) is treated with an agent capable of cleaving the alkyl-aryl ether bond, such as for example a solution of bromidric acid, at high temperature, such as for example  
10 at 110°C. The concentration of the bromidric acid is preferably 48%. The concentration of a compound of formula (IV) into the bromidric acid solution is preferably 0.4M. The progress of this reaction is checked by an analytical method, for example thin layer chromatography or high  
15 performance liquid chromatography or mass spectrometry, and is complete generally within about 5 hours. The above mixture is cooled, preferably at 5°C, and the precipitated compound of formula (V) is filtered and washed with cold water, for example at 5°C. The above wet material is  
20 suspended in water and the mixture is added with a base, such as for example 32% aqueous NaOH, in order to obtain a pH value around 10. The mixture is cooled, preferably at 5°C, and the precipitated compound of formula (V) is filtered, for example with a glass filtering funnel, washed  
25 with cold water, for example at 5°C, and dried, for example under vacuum.

According to step (c) of the above process, the reaction between a compound of formula (V) and the compound of  
30 formula (VI) is carried out by heating, for example at about 100°C, the above compounds in an inert organic solvent, for example toluene, in the presence of acidic substances, for example organic acids such as p-toluensulphonic acid and acetic acid. During the above

reaction the forming water is continuously removed, for example with a stream of nitrogen. The molar ratio between a compound of formula (V) and a compound of formula (VI) is preferably 1 to 1. The catalytic amount of the p-toluenesulphonic acid is preferably 6 mg / mmol of compound of formula (V). The progress of this reaction is checked by an analytical method, for example thin layer chromatography or high performance liquid chromatography or mass spectrometry, and is complete generally within about 7 hours. The above mixture is then cooled, preferably at 25°C, and allowed to stay under stirring for several hours, for example 18 hours, obtaining the precipitation of a compound of formula (I) that is then filtered and dried, for example under vacuum. The so obtained crude material containing a compound of formula (I) is preferably purified by using techniques well known in the art. For example, by slurry in an organic solvent that is capable to dissolve the impurities rather than the desired product of the formula (I), such as for example absolute ethanol, followed by filtration, for example with a sintered glass filtering funnel, and drying for example under vacuum.

According to step (d) of the above process, the reaction between a compound of formula (I) as obtained in step (c) and a compound of formula (VII) as free base as obtained in step (i) is carried out at room temperature, for example at 25°C, in the presence of a base and a solvent. The base can be also the solvent such as for example in the case of using pyridine. The molar ratio between a compound of the formula (I) and a compound of formula (VII) is 1 to 1+2, preferably 1 to 1.5. The progress of this reaction is checked by an analytical method, for example thin layer chromatography or high performance liquid chromatography or mass spectrometry, and is complete generally within about 1

hour. The volatile products are removed with well known methods, for example by means of distillation. The obtained compound of formula (I) as a hydrochloride salt is precipitated by adding an inert organic solvent in which it is not soluble, such as for example n-hexane, and then filtrated, for example with a sintered glass filtering funnel, and dried for example under vacuum. The so obtained crude material containing a compound of formula (I) is preferably purified by using techniques well known in the art, for example, by precipitating the pure corresponding free base by adjusting the pH of the hydrochloride salt aqueous solution to a value of 7 by adding a basic inorganic compound such as, for example, di-potassium hydrogen phosphate. After filtration, for example with a sintered glass filtering funnel, and drying for example under vacuum, a pure compound of formula (I) as a free base is obtained. The hydrochloride salt of a compound of formula (I) can be obtained by dissolving the free base into a hydrochloric acid solution, for example 1N aqueous HCl, and evaporating the solvent for example under vacuum, preferably by lyophilization. The molar ratio between a compound of formula (I) as free base and the acid is preferably 1 to 1.3.

25 According to step (e) of the above process, the reaction between SN-38 and a compound of formula (VII) as free base as obtained in step (i) is carried out in the same way as stated for the above described step (d) obtaining a compound of formula (I).

30

According to step (f) of the above process, the reaction between a compound of formula (I) as obtained in step (c) and the commercially available compound of formula

is carried out in the same way as stated for the above described step (d) obtaining the compounds of formula (I).

5

According to step (g) of the above process, the reaction between a compound of formula (VIII) and a compound of formula (IX) is carried out under an inert atmosphere, for example under nitrogen, by means of a reducing agent, such as for example  $\text{NaBH}_3\text{CN}$  in the presence of a Lewis acid catalyst, such as for example Titanium(IV)isopropoxyde, in an organic solvent, such as for example ethanol, at room temperature, such as for example at  $25^\circ\text{C}$ . It is preferably to pre-mix a compound of formula (VIII) and (IX) with the Lewis acid catalyst without solvents and before adding the reducing agent. The molar ratio among a compound of the formula (VIII), (IX), and the Lewis acid catalyst is preferably 1 to 1 to 1.25. The equivalent ratio between a compound of the formula (VIII) and the reducing agent preferably 1 to 2. The progress of this reaction is checked by an analytical method, for example thin layer chromatography or high performance liquid chromatography or mass spectrometry, and is complete generally within about 20 hours. At the end of the reaction the mixture is added with water, stirred for several hours, for example 4 hours, at room temperature, for example at  $25^\circ\text{C}$ , and then filtered, for example through a sintered-glass filtering funnel recovering the organic solution containing a compound of the formula (X). The crude material containing a compound of formula (X) is recovered by removing the solvents, for example under reduced pressure. The so

obtained crude material is preferably purified by using techniques well known in the art. For example, preparative-column chromatography using silica gel along with appropriate eluants such as mixtures of organic solvents  
5 may be used to effectively purify the desired compound so as the following cleavage of a compound of formula (X) is successfully carried out.

The compounds of formula (VIII) and (IX) are commercially available or can be obtained by applying well-known  
10 procedures in the art.

According to step (h) of the above process, a labeled compound of formula (X) are cleaved by means of an acidic agent, such as for example trifluoroacetic acid, in an  
15 inert organic solvent, such as for example dichloroethane. The reaction is carried out under an inert atmosphere, for example under nitrogen, at room temperature, for example 25°C. The concentration of the acidic reagent into the reaction mixture is about 30÷70, preferably 45% by volume.  
20 The molar ratio of a compound of formula (X) and the acidic reagent is about 1 to 4÷10, preferably 1 to 6.5. The progress of this reaction is checked by an analytical method, for example thin layer chromatography or high performance liquid chromatography or mass spectrometry, and  
25 is complete generally within about 2 hours. At the end of the reaction the mixture is preferably diluted with a base solution in a solvent which is not miscible with the reaction solvent, such as for example 32% aqueous NaOH, up to basic condition of the aqueous layer, for example pH  
30 12÷13. The aqueous layer is extracted with a non-water miscible solvent capable of dissolving the compounds of the formula (XI) such as for example an organic solvent such as for example dichloromethane. The solution containing a compound of formula (XI) is preferably dried, for example

with an inorganic salt such as for example sodium sulphate, and filtered, for example through a sintered glass filtering funnel. The crude material containing a compound of formula (XI) is recovered after solvent evaporation to dryness, for example under reduced pressure.

According to step (i) of the above process, a labeled compound of the formula (XI) is converted into the corresponding carbamoyl chloride hydrochloride of formula (VII) by means of a haloacylating agent, such as for example triphosgene of formula (XIII). The reaction is carried out at low temperature, for example below 10°C and preferably at about 4°C, in an inert organic solvent, such as for example toluene, under an inert atmosphere, for example under nitrogen. The equivalent ratio between a compound of formula (XI) and the haloacylating agent is about 1 to 1 to 5 preferably 1 to 1.8. The progress of this reaction is checked by an analytical method, for example thin layer chromatography or high performance liquid chromatography or mass spectrometry, and is complete generally within about 30 minutes. At the end of the reaction the mixture is filtered, for example through a sintered glass filtering funnel, under an inert atmosphere, for example under nitrogen obtaining the crude material containing a compound of formula (VII) which is recovered as a solid after solvent evaporation to dryness, for example under reduced pressure. The crude material containing a compound of formula (VII) is preferably purified, before the subsequent step (e) or (f), by using techniques well known in the art. For example, by dissolving a compound of formula (VII) in a solvent that does not dissolve the impurities present into the crude material, such as for example dichloromethane. The suspension is filtered, for example through a sintered

glass filtering funnel, under an inert atmosphere, for example under nitrogen, and the collected solution is concentrated, for example at reduced pressure under an inert atmosphere, for example under nitrogen. The  
5 concentrated solution containing a compound of formula (VII) is dripped under an inert atmosphere, for example under nitrogen, to a solvent that poorly dissolves a compound of formula (VII), such as for example methylcyclopentane. At the end of the precipitation the  
10 mixture is filtered, for example through a sintered glass filtering funnel, under an inert atmosphere, for example under nitrogen obtaining the material containing a compound of formula (VII) as a hydrochloride salt which is recovered as a solid after solvent evaporation to dryness, for  
15 example under reduced pressure. A compound of formula (VII) as a hydrochloride salt can be converted into the corresponding free base of formula (VII) by treating its solution into an inert organic solvent that is capable to dissolve the free base, such as for example  
20 dichloromethane, with a base dissolved in water, for example an aqueous solution of an inorganic base, preferably 1M potassium carbonate, at low temperature, for example 0°C. The free base of the formula (VII) is recovered from the organic layer by evaporating the  
25 solvent, for example at reduced pressure.

SN-38 is commercially available or can be obtained by procedures well known in the art, for example following the procedure of K. E. Henegar et al. J. Org. Chem. 62(1997)  
30 6588-97.

The optional salification of a compound of formula (I) may be carried out by conventional methods.

A further object of the present invention is the use of a stable labeled camptothecin analog of formula (I) for ADME studies.

- 5 Another object of the present invention is the use of a stable labeled camptothecin analog of formula (I) as an internal standard in an analytical method for the quantitative detection of the corresponding unlabeled camptothecin derivative in a biological sample.
- 10 A biological sample is preferably a biological fluid, e.g., animal and human plasma, urine, bile, tissues and in vitro cell culture media.

- 15 In a particular aspect, the present invention provides the use of a stable labeled camptothecin analog having the above-identified structures (I') and (I'') as defined in TABLE 1 and TABLE 2 above or a pharmaceutically acceptable salt thereof, as an internal standard in an analytical method for the quantitative detection of the corresponding
- 20 unlabeled camptothecin derivative in a biological sample.

The following Examples 1-17 illustrate the preparation of the compounds (1) to (13) of TABLE 1 of the present invention following the synthetic SCHEME 1 reported below.

**SCHEME 1**

AcOH = acetic acid, DCE = dichloroethane, DCM = dichloromethane, PhMe = toluene, PTSA = p-toluenesulfonic acid

**EXAMPLE 1**

Crude labeled 1-(2-amino-5-methoxy-phenyl)-propan-1-one (IV') where X=CH, Y=W=C, j=CH<sub>2</sub>, Z=CD<sub>3</sub>.

10 To a cold (4°C) stirred solution of boron trichloride in dry dichloromethane (0.92M, 15 ml) prepared under nitrogen, a solution of the compound of formula (II') where X=CH, Y=C (1.5719 g) in toluene (15 ml) was slowly added. This mixture, called reactive A, was kept at 4°C under nitrogen

15 with stirring before its use.

To a cold (10 °C) stirred solution of the labeled compound of formula (III') where, W=C, j=CH<sub>2</sub>, Z=CD<sub>3</sub> (3.1 g) in dichloroethane (10 ml) prepared under nitrogen, aluminum trichloride (2.0720 g) was slowly added. This mixture was

20 slowly heated to 75 °C and kept under these conditions while the whole amount of reactive A was rapidly added. A gentle stream of nitrogen was allowed to pass through the

reactor and the external temperature was increased up to 110°C. When the distillation of dichloromethane and acidic vapors ceased the reaction temperature became stable at 90°C. After about 4 hours the end of the reaction was  
5 checked (by (i) TLC on silica gel 60 with fluorescent indicator at 254 nm plates with thickness of 0.25 mm eluted with dichloromethane-ethyl acetate mixture 98:2 by volume, developing agents = UV light at 254, 336 nm and aqueous permanganate solution; and by (ii). HPLC on C-8 reverse  
10 phase column along with eluants as mixtures of water-acetonitrile-trifluoroacetic acid from 90:10:0.1 to 10:90:0.1 by volume, linear gradient over 13 minutes and 8 minutes of isocratic elution, detection wavelength = 225 nm) and the heating was discontinued. The reaction mixture  
15 was cooled to about 10°C and water (30 ml) was added over 10 minutes under stirring. The clear two-phase brown mixture was heated at 85°C for 30 minutes, and then cooled to room temperature. After phase separation the dark brown organic phase was extracted with further 1N HCl (25 ml x 5  
20 times) then discarded. All the yellow aqueous acidic phases were pooled and slowly added with 35% NaOH up to pH 11. The clear basic aqueous solution was extracted with dichloromethane until a colorless organic extraction phase was obtained (15 ml x 9 times). The organic extracts were  
25 pooled, dried over Na<sub>2</sub>SO<sub>4</sub> and the solvent evaporated under vacuum obtaining an orange yellow oily residue containing the compound of formula (IV') where X=CH, Y=W=C, j=CH<sub>2</sub>, Z=CD<sub>3</sub>). The purity of about 65% was assessed by HPLC (C-8 reverse phase column along with eluants as mixtures of  
30 water-acetonitrile-trifluoroacetic acid from 90:10:0.1 to 10:90:0.1 by volume, linear gradient over 13 minutes and 8 minutes of isocratic elution, detection wavelength = 225 nm), the retention time (Rt = 5.50 minutes) was the same as the retention time of an authentic non-labeled sample.

**EXAMPLE 23**

Purification of the crude material containing labeled  
[1,4']Bipiperidiny1-1'-carbonyl chloride hydrochloride  
5 (XII') where Q=CD<sub>2</sub>, B1=N.

The crude material containing the compound of formula  
(XII') where Q=CD<sub>2</sub>, B1=N (about 0.90 g), prepared for  
example as described in EXAMPLE 22, was added under  
nitrogen with dichloromethane (10 ml) and the resulting  
10 suspension was stirred at room temperature for 15 minutes.  
After adding a filter-aid agent (0.3 g) and stirring for  
further 10 minutes, the suspension was filtered under  
nitrogen collecting the filtrate. The solid was washed with  
dichloromethane (2 x 3 ml) collecting the washings. All  
15 the clear dichloromethane phases were pooled and  
concentrated under a stream of nitrogen at reduced pressure  
up to a total volume of about 4 ml. This solution was  
slowly dripped under nitrogen at room temperature into  
methylcyclohexane (25 ml) with vigorous stirring. The white  
20 suspension was stirred for 20 minutes at room temperature  
under nitrogen then was filtered under nitrogen. The solid  
was washed with methylcyclohexane (3 x 10 ml) then dried at  
room temperature under vacuum for 13 hours. The compound of  
formula (XII') where Q=CD<sub>2</sub>, B1=N (about 0.67 g) was  
25 obtained as a white solid. The purity of about 90% was  
assessed by HPLC (on amino phase column along with eluant  
as mixture of water, containing 3.4 g/l of KH<sub>2</sub>PO<sub>4</sub>, 5.0 g/l  
KCl and H<sub>3</sub>PO<sub>4</sub> up to pH2.2, and acetonitrile in a constant  
ratio of 30:70 by volume), the retention time (Rt = 4.30  
30 minutes) was the same as the retention time of an authentic  
non-labeled sample. The mass spectrum of the title compound  
was recorded using the electrospray ionization technique  
(ESI) with positive ion detection. The ESI mass spectrum  
showed the protonated molecular ions ([M+H]<sup>+</sup>) at m/z 241

amu and also other characteristic ions ( $[M-Cl]^+$ ) at  $m/z$  205 amu. The NMR spectrum recorded in DMSO- $d_5$  at 500 MHz showed the following signals expressed as chemical shifts (ppm): 9.55-9.74 (HCl), s; 4.10-4.34, m; 3.33-3.46 m; 2.93-3.22, m; 2.04-2.17, m; 1.59-1.75, m.
